Solution Implementation (C++)

```
class Solution {
public:
    vector<int> constructRectangle(int area) {

        int closest=1;
        for(int i=1; i*i<=area; i++){    //take 52 as example you
            need a*b=52 and you need min difference between a and b , so a and
            b should be as close to the square root as possible , eg: 36=6*6 ,
            diff=0 hence for every number the difference between factors are
            least if they are as close to square root as possible

            if(area%i==0){
                closest=i;
            }

        }

        int w=closest;
        int l=area/w;

        return {l,w};
    }
};
```
